DESCRIPTION

Erasable and programmable non-volatile cell

The invention relates to an erasable and programmable non-volatile cell, comprising a first transistor having a source, a drain and a gate, a floating capacitor having a floating gate and a control gate, said floating gate being connected to said gate of said first transistor, and means to detect the state, whether erased or programmed, of the cell.

Non-volatile storage is required in a wide range of electronic applications, for example to operate microprocessors and controllers. All floating gate structures use the same basic concept to function that charge stored on the floating gate sets the memory transistor to a logical "1" or "0". Depending on whether the memory structure is an enhancement or depletion transistor, when the floating gate is neutral or contains electrons as negative charge, the memory cell will or will not conduct during read. When the floating gate is neutral or has an absence of negative charge, the memory cell will conduct during read. The conducting or non-conducting state is output as the appropriate logical level. "Erasing" means transferring electrons from the floating gate, "programming" means transferring electrons onto the floating gate.

Various erasable and programmable non-volatile cells are known in the art, among them the so-called flash memories, EEPROMs, or byte alterable E<sup>2</sup>PROMs, each of them based on cell structures, such as the stacked gate cell, where normally programming is performed by drain-side or source-side injection of channel hot electrons through an oxide layer under the floating gate.

The injection of electrons into the floating gate produces a shift in the threshold voltage of the transistor which is proportional to the charge injected into the floating gate. This change of threshold voltage is used as a criterion for defining whether the cell is programmed or erased.

PHCH020023 EP-P

- 2 -

The continuous reduction of the supply voltage necessary to achieve low power consumption in battery powered devices requires a design of cells that can be read at very low supply voltages.

5

In an EPROM cell consisting basically of an n-channel MOS-transistor, the threshold voltage in the erased state, i.e. before programming, normally is in the range of 1.7 to 2.0 V, whereas after programming the threshold voltage increases to 3 to 6 V.

- 10 The spread of the threshold voltage in the erased state, however may become very large, in particular when the cell can only be erased by exposure with ultraviolet radiation. This radiation generates hole-electron pairs in the floating gate which neutralize the injected electrons during programming. The efficiency of this process has inherently a large spread which then produces a corresponding spread in the threshold voltage in the  
15 erased state. This implies that a certain number of cells in a memory array will show a relative large threshold voltage, and cell operation at low voltage from 1.0 to 1.5 V will not be possible. In this case, even the detection of the state of the cell becomes difficult.

- It is the object of the invention to propose an erasable and programmable non-volatile  
20 cell which allows to reliably detect the state of the cell.

This object is achieved by a non-volatile cell as defined in claim 1. Preferred embodiments are subject-matter of the subclaims. Specific applications incorporating the inventive erasable and programmable non-volatile cell are given in claims 6 to 8.

25

According to the invention, said means to detect the state of the cell comprises a second transistor having a source, a drain and a gate, said second transistor being complementary to said first transistor and said gate of said second transistor being connected to said floating gate.

30

PHCH020023 EP-P

- 3 -

"Complementary" means that the second transistor operates with a different type of channel than the first transistor with respect to the floating gate.

In a preferred embodiment the first transistor which is used as programming device is an  
5 n-channel transistor, whereas the second transistor which is used to read the state of the cell is a p-channel transistor. In this case, electrons injected into the floating gate shift the threshold voltage of the cell to more positive values, namely 3 to 6 V for the n-channel transistors and 1 to 3 V for the p-channel transistor. Because a p-channel transistor is used for reading, the natural minimum threshold voltage of the n-channel  
10 transistor does not play any role. The read voltage can be set at the bulk voltage of the p-channel transistor.

Still more preferred, the erasable and programmable non-volatile cell is built up with MOS transistors.

15 It is further proposed to use the polymer-silicon-layer of the MOS transistors also as the floating gate.

Advantageously, the n-well diffusion region is used as said control gate of the floating  
20 capacitor.

This solution makes it possible to use EPROM cells in standard CMOS processes for very low read voltages. The preferred embodiment refers to the cell construction with only one polymer layer. The control gate of the cell is neither a second polymer layer  
25 nor a metal but the n-well diffusion. This feature is inherently available in any CMOS process.

The invention can advantageously be used in liquid crystal display drivers which are very specific integrated circuits which a large extent of analog design. High accuracy is  
30 required in the generation of different voltage levels interacting with the liquid crystal

PHCH020023 EP-P

- 4 -

display. Also the oscillator frequency must be calibrated in a range as narrow as possible.

The non-volatile cell according to the invention can further be used in applications  
5 operating with low supply voltages of about 1.0 V to 2.5 V needed for portable equipment powered by battery, like mobile phones, calculators, pagers, etc.

Cells according to the invention can also be used for calibration of electrical parameters in an integrated circuit.

10 The invention will now be described with reference to the accompanying drawings, wherein

15 Figure 1 illustrates the influence of the spread in threshold voltage when detecting the state of a cell;

Figure 2 schematically shows a non-volatile cell with complementary transistors;

Figure 3 shows the layout of a cell in a first embodiment of the invention;

20 Figure 4 is a cross section taken along A-A' in Figure 3;

Figure 5 is a cross section taken along B-B' in Figure 3;

25 Figure 6 shows the layout of a cell in a second embodiment of the invention;

Figure 7 is a cross section taken along A-A' in Figure 6;

Figure 8 is a cross section taken along B-B' in Figure 6; and

30

PHCH020023 EP-P

- 5 -

Figure 9 shows the process steps to build up a cell according to the first embodiment.

In Figure 1, the drain current  $I_d$  of a single n-channel transistor cell is laid off as  
ordinate, whereas the voltage at the control gate is laid off as abscissa. The  
characteristics of several cells A, B and C which have a spread in their threshold voltage  
are shown. At  $V_{cg} = 1.5$  V, cell A will be read as "erased", cells B and C will be  
detected as "programmed". This fundamental disadvantage is inherent to those cells and  
is overcome by the invention.

Figure 2 schematically shows a cell according to the invention consisting of an n-  
channel transistor 10 and a p-channel transistor 20 having a common floating gate 30  
and control gate 40. N-channel transistor 10 is used as a programming device. The  
programming mechanism is based on the hot electrons phenomena that occurs when the  
transistor is operated in its saturation region. P-channel transistor 20 is used to read the  
state of the cell. Electrons injected into the floating gate 30 shift the threshold voltage of  
the cell to more positive values, namely 3 to 6 V for n-channel transistor 10 and to 1 to  
3 V for p-channel transistor 20. Both transistors preferably are MOSFETs. With this  
configuration, the drain currents of each transistor at erased and programmed states are  
separated to be unambiguously distinguished from one another.

The layout of a cell according to a first embodiment of the invention is represented in  
figure 3. Cross sections taken along A-A' and B-B' in figure 3 are shown in figure 4 and  
figure 5, respectively. N-channel transistor 10 and p-channel transistor 20 share a  
common floating capacitor FT. The floating gate 30 and the gates of n-channel and p-  
channel transistors 10, 20 are embodied as a polylayer. Floating capacitor FT is  
completed by a control gate 40 overlying floating gate 30 separated by an oxide or  
oxide/nitride layer 50.

30

PHCH020023 EP-P

- 6 -

Figure 6 shows the layout of a cell according to a second embodiment of the invention. In Figures 7 and 8, respectively, cross sections taken along A-A' and B-B' are illustrated. In comparison to the embodiment of Figures 3 to 5, the n-well diffusion region is extended to used as the control gate 40 separated from the floating gate 30 by 5 an oxide layer 50.

Thus, the implementation of this cell is not restricted to CMOS processes with floating capacitors, but is also applicable for single polylay CMOS processes. No changes in the process flow are necessary. EPROM cells for very low read voltages can be 10 implemented in any CMOS process.

The non-volatile cells according to the invention can also be used to design memory arrays. Here, a select transistor in series with the p-channel transistor has to be included.

15 Figure 9 shows an example of a process flow to build up a cell according to the first embodiment of the invention. With a slight modification, it is also possible to use the process flow to build up a cell according to the second embodiment of the invention.

In step (a) a substrate made of p-doped silicon (p-Si) is prepared and subjected to field 20 thermal oxidation to build up an oxide layer on said substrate. Active areas are defined therein which will form gates for the n- and p-transistors.

In step (b), the N-well is implanted under the gate oxide layer which will later be used for the p-channel transistor, and driven in at a temperature of about 1150°C.

25 In step (c), n<sup>+</sup> poly-silicon is deposited on certain areas of the oxide layer to define gate areas of p-channel (p-ch) transistor and n-channel (n-ch) transistor and the control gate.

Thereafter, in step (d) source and drain are formed for n- and p-channel transistors.

30

In step (e), a dielectric layer comprised of  $\text{SiO}_2$  in a thickness of 20 nm which is achieved by polyoxidation, and of  $\text{SiO}_3\text{N}_4$  having a thickness of 300 nm, obtained by low pressure CVD deposition is build up on the exposed surface of the structure.

5

In step (f) oxide in a thickness of 1000 nm is deposited over the dielectric layer, thereafter, the cell is planarized by CMP technology.

10 In step (g), the opening for the coupling capacitor area is defined by photolithography and then realized by etching the oxide over the desired area.

In a similar process, shown in step (h), the contact holes to sources and drains of the two transistors are provided. Again, photolithography techniques and oxide etching can be used.

15

In step (i), the contact holes are filled with conducting material.

20 In step (j), the interconnection is provided by sputtering aluminum/copper (Al/Cu) onto the entire surface, defining contact areas by photolithography and realizing the desired interconnection by etching unnecessary metal portions away.

In a similar manner, the cell of the second embodiment can be realized by providing the N-well region in a suitable manner and by rearranging the interconnections.

25 The operation of a complementary EPROM cell according to the invention will be explained briefly in the following. An n-channel MOS-transistor is used for programming, and a p-channel MOS is used for reading. Programming is performed by channel hot electron injection. To achieve this, the n-channel MOS-transistor has to be operated in saturation which means a drain voltage  $V_d$  in a range between 7.0 to 10.0 V  
30 and a control gate voltage  $V_{cg}$  in a range of 7.0 to 9.0 V. The optimum condition for

PHCH020023 EP-P

- 8 -

programming is given for  $V_d$  and  $V_{eg}$  that produce a maximum substrate current. Typical reading voltages of  $V_d$  for low voltage applications are in the range of 1.5 to 2.5 V.

	$V_d$ (n-ch)	$V_{eg}$	$V_d$ (p-ch)
Programming	7.0	8.0	floating
Read	floating	$V_{dd}$	1 to 2.5 V

CLAIMS

1. An erasable and programmable non-volatile cell, comprising

- a first transistor (10) having a source, a drain and a gate;
- a floating capacitor (FT) having a floating gate (30) and a control gate (40), said floating gate being connected to said gate of said first transistor; and
- means to detect the state, whether erased or programmed, of the cell;

5 characterized in that said means to detect the state of the cell comprises a second transistor (20) having a source, a drain and a gate, said second transistor (20) being complementary to said first transistor (10) and said gate of said second transistor being connected to said floating gate (30).

10 2. The cell according to claim 1, characterized in that said first transistor (10) is an n-channel transistor and said second transistor (20) is a p-channel transistor.

15

3. The cell according to claim 2, characterized in that said first and second transistors (10, 20) are MOSFET transistors.

20

4. The cell according to any of claims 1 to 3, characterized in that the n-well diffusion region of said p-channel transistor (20) is the control gate (40) of said floating capacitor.

PHCH020023 EP-P

- 10 -

5. The cell according to any of claims 1 to 4, characterized in that said floating gate (30) and the gates of said first (10) and second (20) transistors are embodied as single polymer layer.

5

6. Liquid crystal display driver, comprising a non-volatile cell according to any of claims 1 to 5.

7. Portable equipment powered by battery, such as mobile phones, calculators, pagers, comprising a non-volatile cell according to any of claims 1 and 5.

10

8. Use of non-volatile cells according to any of claims 1 to 5 for calibration of electrical parameters in an integrated circuit.

15

PHCH020023 EP-P

ABSTRACT

Erasable and programmable non-volatile cell

An Erasable and programmable non-volatile cell, comprising

- 5      - a first transistor having a source, a drain and a gate;
  - a floating capacitor having a floating gate and a control gate, said floating gate being connected to said gate of said first transistor; and
  - means to detect the state, whether erased or programmed, of the cell;
- 
- 10     is characterized in that said means to detect the state of the cell comprises a second transistor having a source, a drain and a gate, said second transistor being complementary to said first transistor and said gate of said second transistor being connected to said floating gate.
